

Generalized entropy bound: $\lambda_{\min}$ is a sampled distribution, not a point value

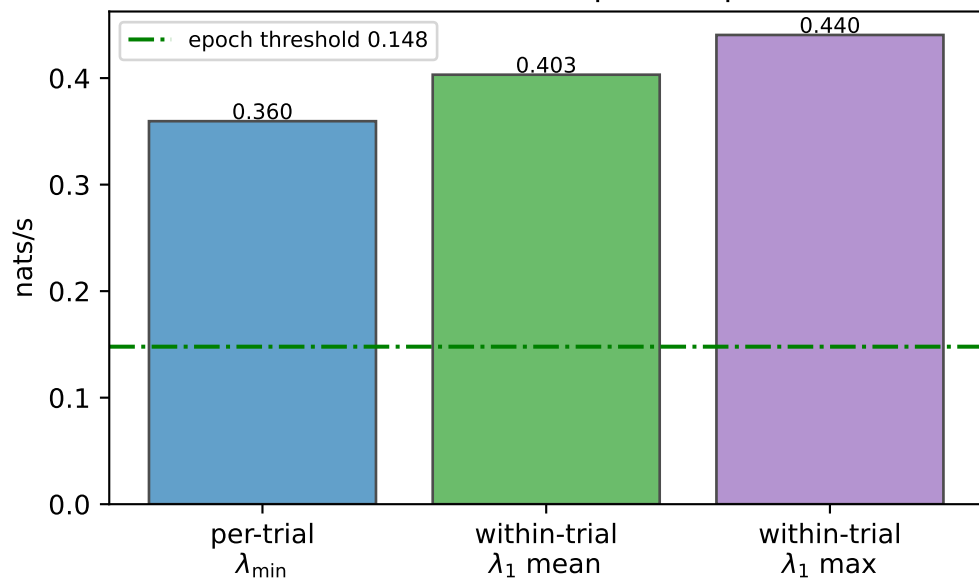

(a) $\lambda_{\min}$ across 10 attractor trials

(b) 256-bit accumulation fits within the epoch

(c) conservative tail vs per-sample mean

Bounded wrapped coupling (ADR-004, $c=1.0$) with the corrected tangent update (f68bdc5): the former spurious 60-75 nats/s high band is gone (`highband_frac = 0`, all trials). $\lambda_{\min}$ is the finite-time minimum over 1000 sampled ICs at $T=2000$ s (10 trials). Worst trial $\lambda_{\min} \approx \text{lam.min()} : .3f \Rightarrow dt_{\text{bound}} \approx 573$ s, comfortably inside the 1200 s epoch. The regime is robustly chaotic: verified basin minimum ~ 0.379 at $T=2000$ -8000 s. Fixed-point discretization floor caveat applies (ADR-003).
