

Generalized entropy bound: $\lambda_{\min}$ is a sampled distribution, not a point value

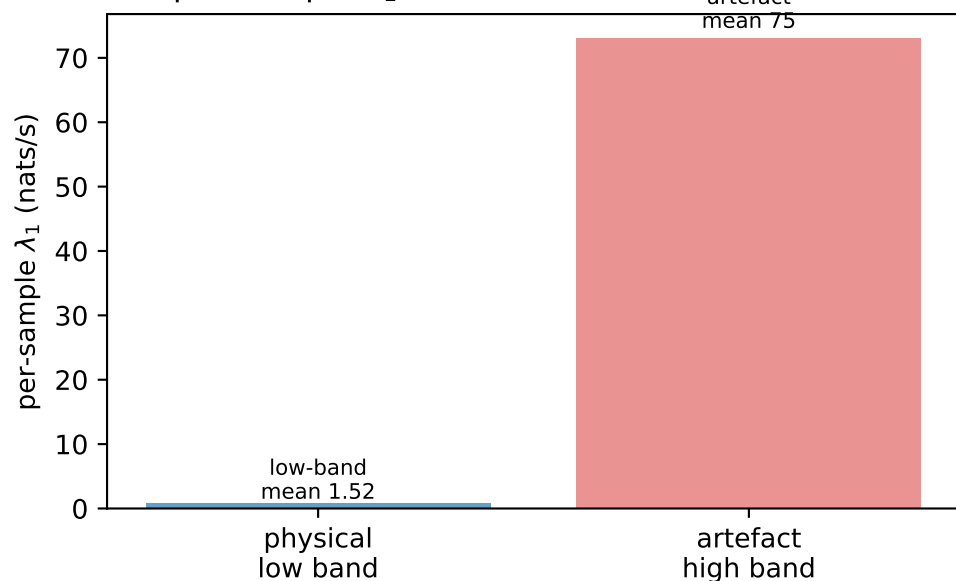

(a) $\lambda_{\min}$ across 10 attractor trials

(b) entropy bound is conservative

(c) per-sample λ_1 is bimodal (15% in artefact band)

Per-sample λ_1 is bimodal.
 ~15% of draws land in a spurious high band (60–75 nats/s) caused by fixed-point blow-up in the tangent update, not a physical attractor. The conservative $\lambda_{\min}$ is always drawn from the physical low band (mean $\approx \text{ lows.mean() } : .2f$ nats/s), so the entropy bound below is unaffected by, and independent of, the artefact band.
